CORPORATE DISCLOSURE STATEMENT

National Birth Equity Collaborative is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of NBEC.

National Medical Association is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of NMA.

American Medical Association is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of AMA.

Medical Society of the State of New York is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of MSSNY.

American College of Physicians is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of ACP.

American Public Health Association is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of APHA.

Council of Medical Specialty Societies is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of CMSS

New York State Academy of Family Physicians is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of NYSAFP.

Community Service Society of New York is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of CSSNY.

Housing Works is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of Housing Works.

Callen-Lorde Community Health Center is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of Callen-Lorde.

Partners in Health is a non-profit entity and has no parent corporation. No publicly owned corporation owns 10% or more of the stocks of Partners in Health.

TABLE OF CONTENTS

INTRODUCTION 1

ARGUMENT 2

I. Minoritized populations are at heightened vulnerability to severe illness and death from COVID-19..... 2

 A. Minoritized populations have experienced disproportionately high rates of serious illness and death from COVID-19. 2

 B. Minoritized populations have disproportionately higher rates and severity of medical conditions that increase the risk of developing severe COVID-19 symptoms. 5

 C. Black and Latinx people have disproportionately higher rates of certain COVID-19-related complications. 6

II. The higher rates of severe symptoms and death from COVID-19 experienced by minoritized people are tied to systemic racism and bias, and are not accounted for by other observable risk factors. 7

 A. Social drivers of health caused the COVID-19 pandemic to disproportionately harm minoritized populations. 8

 B. BIPOC individuals receive lower quality healthcare and reduced access to treatments than whites due to medical racism and bias. 17

III. Because social inequities and racism exacerbate COVID-19 morbidity and mortality in minoritized populations, considering a patient’s BIPOC race or ethnicity in evaluating their risk of severe progression is justified. 21

INTRODUCTION

Amici are leading medical, health equity, and social science experts as well as organizations with direct experience on the frontlines of the COVID-19 pandemic, including in New York. *Amici* submit this brief to underscore the substantial medical and scientific literature that supports the New York Department of Health’s acknowledgment that “longstanding systemic health and social inequities have contributed to an increased risk of severe illness and death from COVID-19” for people of “[n]on-white race or Hispanic/Latino ethnicity.”¹ Although race is not an inherent genetic or biological trait and therefore does not *genetically* contribute to a higher risk of medical conditions, there is no serious medical or public health dispute that longstanding systemic health and social factors have led to a disproportionately higher burden of COVID-19, including exposure, infection, severe illness and death, among populations marginalized and minoritized by systems and structures, including Black, Native American, Indigenous, Latinx, Asian American, Pacific Islander American, and people of color (BIPOC individuals).² *Amici* further submit this brief to outline for the Court the existing inequities in access to prevention, care, and treatment for COVID-19 that show that the public interest supports the Department’s non-binding guidance that medical professionals, in exercising their independent clinical judgment and discretion, consider a COVID-19 patient’s BIPOC race or ethnicity alongside other relevant factors when evaluating a

¹ N.Y. State Dep’t of Health, *Prioritization of Anti-SARS-CoV-2 Monoclonal Antibodies and Oral Antivirals for the Treatment of COVID-19 During Times of Resource Limitations*, at 3 (Dec. 29, 2021) [hereinafter *Prioritization Guidance*]; N.Y. State Dep’t of Health, *Memorandum Re: COVID-19 Oral Antiviral Treatments Authorized and Severe Shortage of Oral Antiviral and Monoclonal Antibody Treatment Products* 3 (Dec. 27, 2021) (“[L]ongstanding systemic health and social inequities put Black, Indigenous, and People of Color at increased risk of severe COVID-19 outcomes and death.”).

² As used in this brief, BIPOC is meant to refer to populations and individuals with races and ethnicities that have been historically minoritized and marginalized by systems and structures.

COVID-19 patient's risk of progressing to severe illness.

ARGUMENT

I. Minoritized populations are at heightened vulnerability to severe illness and death from COVID-19.

For two years, the COVID-19 pandemic has wreaked havoc in communities across the country, upended the lives of countless families, and killed more than 68,000 New Yorkers.³ Although the COVID-19 pandemic has taken a toll on all New Yorkers, it has disproportionately impacted minoritized populations. For example, Latinx populations have experienced higher rates of SARS-CoV-2 infection than white populations, and BIPOC populations have experienced higher rates of severe COVID-19 symptoms, serious illness requiring hospitalization, and death from COVID-19 than whites.

A. Minoritized populations have experienced disproportionately high rates of serious illness and death from COVID-19.

Minoritized populations have experienced disproportionately high rates of death from COVID-19.⁴ Based on data collected through March 7, 2021, Black individuals have died from COVID-19 at 1.4 times the rate of white individuals.⁵ One study found that, among individuals aged 25–54, the *Black and Latinx populations lost nearly 7 times, and the Indigenous population lost nearly 9 times, as many years of life before age 65 from COVID-19 as the white population.*⁶ “[W]hile Asian Americans make up a small proportion of COVID-19 deaths in the USA, they

experience significantly higher excess all-cause mortality (3.1 times higher), case fatality rate (as high as 53% higher), and percentage of deaths attributed to COVID-19 (2.1 times higher) compared to non-Hispanic Whites.”⁷ The disproportionately higher mortality rates for BIPOC people remain even after accounting for differences in level of education.⁸ The inequity is stark:

If all groups had experienced the same mortality rates as college-educated non-Hispanic White individuals, there would have been 48% fewer COVID-19 deaths among adults aged 25 years or older overall, including 71% fewer deaths among racial and ethnic minority populations and 89% fewer deaths among racial and ethnic minority populations aged 25 to 64 years.⁹

In New York State, according to a 2020 study, Black individuals comprised 16% of the population but made up 22% of COVID-19 deaths statewide;¹⁰ Latinx individuals comprised 19% of state residents, but made up 24% of statewide COVID-19 deaths.¹¹ By contrast, whites comprised 55% of New York State’s population, but made up 43% of statewide COVID-19 deaths.¹² According to recent data from New York State, the COVID-19 death rate for whites has been 155 per 100,000, whereas the death rates for Asian American, Black, and Latinx people has been 186, 349, and 269 per 100,000, respectively.¹³ Outside of New York City, the age-adjusted death rate “is double or even quadruple for [Black], Latinx, and Asian New Yorkers” relative to

white New Yorkers.¹⁴ In fact, after adjusting for age, *New York is the state with the highest COVID-19 mortality rate among its Black residents.*¹⁵

Indeed, from the earliest days of the COVID-19 pandemic, minoritized individuals have been disproportionately impacted. In New York City, the initial epicenter of the pandemic, the COVID-19 case rates in majority Black, Latinx, and other communities marginalized by systems and structures was between 24% and 110% higher than those in majority white communities¹⁶ before leveling out, although Latinx communities still experience significantly higher infection rates than whites.¹⁷

More significantly, BIPOC people experience disproportionately higher rates of severe illness from COVID-19.¹⁸ As of March 2021, the COVID-19 hospitalization rate of Asian Americans, Latinx, and Black New Yorkers was 2.5, 3.8, and 4.2 times that of white New Yorkers, respectively.¹⁹ One study found BIPOC people experience higher rates of COVID-19 disease

See Gbenga Ogedegbe et al., *Assessment of Racial/Ethnic Disparities in Hospitalization and Mortality in Patients With COVID-19 in New York City*, JAMA Network Open, Dec. 4, 2020, at 2, bit.ly/3uRdjZB; Rafi Kabarriti et al., *Association of Race and Ethnicity With Comorbidities and Survival Among Patients With COVID-19 at an Urban Medical Center in New York*, JAMA Network Open, Sept.

severity upon admission to a hospital compared with whites, which increases the likelihood of needing intubation or ICU care, and death.²⁰

B. Minoritized populations have disproportionately higher rates and severity of medical conditions that increase the risk of developing severe COVID-19 symptoms.

Heart disease and diabetes are two of the most common underlying medical conditions that the U.S. Centers for Disease Control and Prevention (CDC) has recognized place patients with COVID-19 at increased risk for severe illness or death,²¹ and these diseases disproportionately affect BIPOC individuals, including in New York.²² BIPOC people also experience higher rates of undiagnosed medical conditions (including diabetes),²³ thus increasing the likelihood of having a risk factor that goes undetected. And among people diagnosed with medical conditions such as diabetes or heart disease, BIPOC people experience higher rates of more severe cases, disease-

25, 2020, doi.org/10.1001/jamanetworkopen.2020.19795. These studies were limited to individual hospitals; recognized the disparate hospitalization and mortality rates for Black COVID-19 patients in other studies; and proposed explanations for their unexpected results, such as differential COVID-19 testing or rates of insurance.

²³ See CDC, *Prevalence of Both Diagnosed and Undiagnosed Diabetes*, *supra* note 22.

related complications, and premature death from those diseases, than their white counterparts.²⁴ Consistent with this evidence, a study found that “racial disparities in COVID-19 outcomes exist despite comparable ECIs [comorbidities] among” patients.²⁵ The researchers calculated that Black patients in the sample had 1.72 times the odds of invasive ventilator dependence than white patients, and Indigenous patients had 2.06 times the odds of death than white patients.²⁶

C. Black and Latinx people have disproportionately higher rates of certain COVID-19-related complications.

Studies have found that Black and Latinx people experience higher rates of certain serious COVID-19 related complications than white individuals. For example, according to one study of several hospitals in and around New York City, 37% of patients hospitalized for COVID-19 develop acute kidney injury, which significantly increases the likelihood of death.²⁷ The study further found that Black patients were more likely than white patients to develop acute kidney injury.²⁸ Similarly, studies conducted in both New York City and New York State found that more than 70% of all reported cases of multisystem inflammatory syndrome in children—“a rare but severe condition that occurs approximately 2–4 weeks after the onset of COVID-19 in children

and adolescents”—have occurred among Black or Latinx children.²⁹

II. The higher rates of severe symptoms and death from COVID-19 experienced by minoritized people are tied to systemic racism and bias, and are not accounted for by other observable risk factors.

Extensive literature provides two well-supported explanations for the racial and ethnic inequities in COVID-19 case severity and mortality. First, the legacy of this country’s long history of racist policies—such as segregation and persistent inequities in housing, employment, access to healthcare, health care, and other life opportunities—has led to adverse health outcomes for racial and ethnic groups historically marginalized by systems and structures.³⁰ Social factors, known as “social determinants of health,” and systemic factors such as exposure to racism, are both “social drivers of health,” which establish that societal conditions can—and do—affect an individual’s health risk.³¹ Second, racism and implicit bias within the medical system has resulted in lower quality healthcare for BIPOC individuals.³² Crucially, these systemic inequities manifest in an increased risk of developing severe COVID-19 symptoms relative to whites—a risk that is not captured by other immediately observable information such as age, vaccination status, and presence of underlying medical conditions.³³

A. Social drivers of health caused the COVID-19 pandemic to disproportionately harm minoritized populations.

The COVID-19 pandemic's disparate impact is neither novel nor a coincidence. Racial and ethnic disparities in health outcomes are well documented. For example, Black individuals "are three times as likely as whites to develop cardiovascular disease and are twice as likely to die from it."³⁴ In 2017, the rate of asthma deaths among adults aged 65 and older was significantly higher for Black Americans, Asian Americans, and Pacific Islander Americans than for whites.³⁵ And Black women are nearly three times as likely as white women to die from pregnancy-related complications.³⁶ Inequities in health outcomes persist "even when access-related factors, such as patients' insurance status and income, are controlled."³⁷ To illustrate, a study found that "[t]he PRMR [pregnancy-related mortality ratio] among black women with a completed college education or higher was 1.6 times that of white women with less than a high school diploma."³⁸ It is crucial to note that "these disparities do not arise from bad individual choices or biological differences between races but the social factors that shape people's lives every day We as a society have created them."³⁹

Numerous social drivers of health have historically prevented people of color, and Black individuals in particular, from having the same opportunities to attain good physical health as white individuals.⁴⁰ Inequitable living, working, and other life conditions can negatively impact an individual's health in obvious ways. Living in heavily polluted areas may worsen one's asthma, for example.⁴¹

Across all social drivers of health, however, stress is a primary pathway for disparate health outcomes. Racism, discrimination, and inequitable living circumstances can cause chronic stress, which is linked to a wide array of poor health outcomes through various psychophysiological pathways.⁴² Chronic stress “degrades physiological systems,” resulting in “greater susceptibility to pathogens” and decreased “effectiveness of the immune system and resistance to infections, leading to serious illnesses.”⁴³ Researchers “have documented a direct link between social stress and sickness, with stressful life events predicting illnesses as serious as heart disease.”⁴⁴ Researchers have similarly documented an association between chronic stress and elevated blood pressure.⁴⁵

i. Racially segregated communities as a social driver of health.

Living in a racially segregated community is a prime example of a negative social determinant of health. Poverty is concentrated in racially segregated areas,⁴⁶ and poverty is linked to adverse health outcomes. Children who live in poverty are “two to four times more likely to have a disease than children who do not.”⁴⁷ Housing in segregated communities is disproportionately poorer quality and more crowded.⁴⁸ Racially segregated neighborhoods also have lower quality schools, another factor linked to adverse health outcomes.⁴⁹ Segregation has also been linked to later-stage diagnosis of cancers and lower cancer survival rates.⁵⁰ New York City is one of the most racially segregated metropolitan areas in the country. Most of Long Island’s Black residents live in just 11 of the island’s 291 communities.⁵¹ And almost 90% of Brooklyn’s Black residents live in segregated neighborhoods.⁵² As discussed further below, access to healthcare services is also restricted in racially segregated neighborhoods.

ii. Access to healthcare as a social driver of health.

Communities of color experience disproportionately low access to healthcare services compared to white Americans. One study found that “[c]ommunities with high proportions of [B]lack and Hispanic residents were four times as likely as others to have a shortage of physicians,

regardless of community income.”⁵³ In New York, numerous policies over the past several decades have resulted in underfunded and under-resourced hospital systems in communities of color.⁵⁴ For example, when the state “cut thousands of hospital beds” in 2016, a disproportionate number were in communities that served people of color and underinsured individuals, exacerbating the COVID-19 pandemic’s impact on those communities.⁵⁵ “Many of the same neighborhoods with high rates of COVID-19 infections and poor primary care access are low-income neighborhoods of color and experience higher rates of chronic diseases that are best managed by primary care providers.”⁵⁶ According to data from 36 hospitals in New York, “patients at some community hospitals were three times more likely to die as patients at medical centers in the wealthiest parts of the city,” due to vast disparities in available treatments, staffing levels, and supplies.⁵⁷

Although BIPOC communities in New York have experienced disproportionately high rates of severe illness and death from COVID-19 from the earliest days of the pandemic, those communities “were not included in vaccine priority plans crafted by the state and city.”⁵⁸ For example, a study showed that “early COVID-19 vaccination efforts in NYC [were] focused primarily in White, middle-to-upper class neighborhoods, with the greatest access occurring in

those areas.”⁵⁹ The vaccine rollout in New York City was “plagued by stark racial disparities, with Black and Latino residents receiving far fewer doses than white residents.”⁶⁰ Gaps in New York City’s COVID-19 response policy resulted in inadequate access to COVID-19 testing to communities of color.⁶¹ A September 2021 study in New York City observed that “racial disparities in access to [COVID-19] testing remain as of today, despite the need for testing in communities that experience a large number of essential workers living in crowded realities.”⁶²

Treatment options may also be limited in racially segregated communities. Despite experiencing higher rates of severe illness and death from COVID-19, BIPOC patients have been less likely than white patients to receive monoclonal antibody therapies (mAb). A recent large-scale study that included several healthcare facilities in New York found that Latinx, Black, Asian American, and other patients of color received mAb 58%, 22%, 48%, and 47% less often, respectively, than white patients.⁶³ The study concluded that, “as a consequence of [BIPOC people’s] higher prevalence of preexisting conditions,” the mAb treatment inequity “amplif[ies] the increased risk for severe COVID-19–associated outcomes, including death among these groups.”⁶⁴ The CDC identified several access-related factors as potential explanations for the

⁶⁴ *Id.* at 100.

documented racial and ethnic inequities in COVID-19 mAb treatment, including “systemic factors such as limited access to testing and care because of availability constraints, inadequate insurance coverage, and transportation challenges; lack of a primary care provider to recommend treatment; variations in treatment supply and distribution; potential biases in prescribing practices; and limited penetration of messaging in some communities about mAb availability and effectiveness to prevent disease progression.”⁶⁵

iii. Working conditions as a social driver of health.

Racial and ethnic inequities in employment opportunities lead to adverse health outcomes for several reasons. Overall, individuals in minoritized groups have disproportionately lower-paying jobs, leaving them with less money to spend on healthcare.⁶⁶ They are also more likely to work in jobs that cannot be done remotely from home, such as health care, service and retail occupations, and to have longer commute times on public transportation, increasing their exposure to infectious diseases like COVID-19.⁶⁷

BIPOC individuals are also less likely to hold jobs that provide health insurance, and are therefore “significantly more likely to be underinsured than the white population.”⁶⁸ Many New Yorkers lost their health coverage during the pandemic, but “African Americans in New York City reported losing health insurance twice as often,” and “Latinx New Yorkers reported losing health insurance nearly four times as often,” as white New Yorkers.⁶⁹ Researchers have cited social

determinants of health, including lack of paid time off and lack of insurance, as barriers to COVID-19 vaccine access and accommodations.⁷⁰

iv. Exposure to racism as a social driver of health.

Exposure to racial and ethnic discrimination in daily life is a significant social driver of health. Extensive research has documented that racism itself negatively impacts health over time through a process called weathering.⁷¹ A review of 138 empirical studies on the health effects of racism showed a clear link between racism and ill health for oppressed racial groups, even after adjustment for confounding factors.⁷² Another meta-analysis of 293 studies concluded that “racism is significantly related to poorer health.”⁷³ In a 2011 study, more than 90% of Black individuals reported having experienced racial discrimination.⁷⁴ Racial discrimination can cause chronic stress, which, as noted, is linked to a wide array of poor health outcomes. A study found that exposure to discrimination and segregation during juvenile years predicts adult inflammation by age 28, and that the effect was “considerably more robust than that of traditional health risk factors such as diet, exercise, smoking, and low [socioeconomic status].”⁷⁵ Racial discrimination need not

be intended: “[e]vidence has revealed that unconscious bias in interpersonal interactions is strong, widespread and deeply rooted, and could potentially take a heavy toll on health.”⁷⁶

v. *Incarceration and homelessness as social drivers of health.*

Incarceration and homelessness are two additional social determinants of health that disproportionately impact people of color. Black individuals have higher rates of incarceration than white individuals who commit the same offense.⁷⁷ In New York, Black individuals are imprisoned at a rate that is over three times their percentage of the state’s population.⁷⁸ Imprisoned people are exposed to more infectious diseases and to significant stress, yet prisons rarely “provide much beyond the most basic medical care.”⁷⁹ The increased likelihood of having disease while imprisoned does not end upon release; a history of incarceration also “strongly increases the chances of severe health limitations after release.”⁸⁰ Prisons have been epicenters of COVID-19 outbreaks since the beginning of the pandemic.⁸¹ Additionally, people experiencing homelessness in New York experienced higher rates of death from COVID-19 in both congregate shelter and unsheltered settings.⁸² Minoritized people are disproportionately represented among homeless

effects of social-environmental exposures,” better explains the “persistence of [cardiovascular disease] disparities between members of socially imposed racial categories” than does genetics.).

populations.⁸³

- vi. *Social drivers of health have led to disproportionately high rates of serious illness and death from COVID-19 for BIPOC people.*

Researchers have repeatedly concluded that social determinants of health contribute to BIPOC peoples' disproportionate rates of severe illness and death from COVID-19, across the country and in New York.⁸⁴ An individual's job opportunities and work conditions, access to healthcare, exposure to racism, and segregated living conditions often go hand in hand, leading to a cumulative increase in risk of severe illness or death from COVID-19 associated with a person's BIPOC race or ethnicity.⁸⁵ For an individual, inequitable social determinants of health may manifest, for instance, in high blood pressure, increased inflammation, and earlier onset of, and

⁸⁵ See, e.g., Nicholas Verdini et al., *supra* note 84, at 284 ("The Hispanic population has been shown to experience discrimination, inadequate healthcare access and utilization, inequities in education access, wealth gaps, and increased congested housing, all of which increase the risk of contracting COVID-19.").

more severe forms of, medical conditions such as heart disease, thereby compounding the risk of getting severely ill or dying from COVID-19 in a way that is not captured by consideration of the presence of heart disease alone. At bottom, “conditions of marginalization led, before COVID-19, to higher morbidity and mortality among Black Americans, which then resulted in a higher burden of underlying vulnerability to COVID-19, manifesting in disproportionate disease severity and death.”⁸⁶ The same is true of other minoritized populations.⁸⁷

B. BIPOC individuals receive lower quality healthcare and reduced access to treatments than whites due to medical racism and bias.

Racism against BIPOC individuals within the healthcare system also results in adverse health outcomes and makes race and ethnicity itself, as a proxy for racism, worth consideration, along with other relevant factors, by medical professionals exercising independent judgment to determine the appropriate COVID-19 treatment.⁸⁸

Healthcare disparities are “differences in treatment experienced in the quality of healthcare received by racial and/or ethnic minorities even when access to care is equal.”⁸⁹ Numerous studies show that BIPOC patients receive lower quality treatment by healthcare providers, “even when variations in such factors as insurance status, income, age, co-morbid conditions, and symptom expression are taken into account.”⁹⁰ The research links these racial and ethnic differences in treatment to adverse health outcomes for BIPOC individuals. The following sample of racial and ethnic healthcare inequities illustrates their severity:

- Black patients and other minoritized patients are less likely than whites to receive

preventive care and routine medical procedures.⁹¹

- Black patients are treated less for pain than white patients.⁹² For example, “sickle-cell patients who are in severe pain waited longer in emergency rooms to get pain medication than white patients with a similar painful disease (for example, renal colic).”⁹³
- Minoritized patients are sometimes denied care due to racially biased algorithms. For example, due to racial biases in pulse oximeter technology, Black patients have nearly three times the frequency of undetected low oxygen levels than white patients, which can negatively impact Black patients’ treatment for COVID-19.⁹⁴
- Black patients are less likely than white patients to receive kidney transplants.⁹⁵ Race-based kidney function adjustments based on false ideas about differences in muscle mass have denied Black people access to dialysis and transplants.⁹⁶
- Doctors are almost twice as likely to refer white patients to a specialist than they are to refer Black patients.⁹⁷
- Black and Latinx individuals are less likely to receive appropriate cardiac medication or to undergo cardiac bypass surgery than whites.⁹⁸ Although Black individuals are three times as likely to develop cardiovascular disease than whites, and twice as likely to die from it, they are more likely than whites “to receive older conservative coronary treatments than newer or more expensive therapies . . . [which are] more readily available to whites.”⁹⁹

Extensive research shows that healthcare inequities are due not to intrinsic clinical factors, but to exposure to racism within the medical system.¹⁰⁰ One recent study found, for example, that

“many white medical students and residents”—73% of the study sample—“hold beliefs about biological differences between blacks and whites, many of which are false and fantastical in nature, and that these false beliefs are related to racial bias in pain perception.”¹⁰¹ Another study found that among children who visited emergency departments, Black and Latinx children were less likely to “have their care needs classified as immediate/emergent” and “experienced significantly longer wait times and overall visits as compared to whites.”¹⁰² The researchers concluded the “difference could not be fully explained by possible confounding factors available in the dataset, such as demographic, socioeconomic, or clinical variables.”¹⁰³ Additionally, “Black newborns have significantly lower mortality if they’re cared for by Black doctors rather than white ones.”¹⁰⁴ Another study of 495 largely white, male physicians found that they were less likely to prescribe an aggressive HIV treatment to Black men than white men due to negative racial bias.¹⁰⁵

In 2007, researchers produced “the first evidence of unconscious (implicit) race bias among physicians, its dissociation from conscious (explicit) bias, and its predictive validity.”¹⁰⁶ The researchers concluded that physicians’ implicit bias contributed to racial and ethnic disparities in the use of medical procedures such as thrombolysis for myocardial infarction.¹⁰⁷ The study also

¹⁰⁷ *Id.*

showed that as physicians' IAT (implicit bias) scores increased, their likelihood of treating Black patients with thrombolysis decreased. A 2015 systematic review of 15 studies measuring implicit bias and health outcomes confirmed that healthcare professionals hold the same level of implicit bias against Black, Latinx, and dark-skinned people as the general population, and that "implicit bias was significantly related to patient-provider interactions, treatment decisions, treatment adherence, and patient health outcomes."¹⁰⁸ A 2017 systematic review of 37 studies confirmed the substantial evidence of "pro-White or light-skin/anti-Black, Hispanic, American Indian or dark-skin bias among a variety of [healthcare professionals] across multiple levels of training and disciplines."¹⁰⁹

Research has shown that a person can "hold strongly negative implicit biases" even where they express no explicit bias and believe themselves to be race-neutral.¹¹⁰ Studies show that implicit bias influences behavior more directly than conscious bias does.¹¹¹ The evidence reveals that "implicit race biases are as prevalent among professionals in the health care industry as they are among the American public generally."¹¹² Most healthcare professionals, like most whites, "are low in explicit and high in implicit" bias.¹¹³ In other words, many healthcare professionals unconsciously hold negative biases against BIPOC groups, and these negative biases may cause them to provide—entirely unintentionally—a lower quality of care to their BIPOC patients than

they might provide to similarly situated white patients. Research has shown that strategies based on ignoring group differences do not eliminate bias, whereas making healthcare professionals aware of their own biases and stereotypes does.¹¹⁴ Researchers have concluded that “[i]nterventions targeting implicit attitudes among health care professionals are needed.”¹¹⁵

Consistent with this evidence, the CDC has identified “potential biases in prescribing practices” as one reason for the observed racial and ethnic disparity in mAb treatment.¹¹⁶ The New York City Health Department has recognized that “race norming . . . often negatively impacts the treatment and care for persons of color.”¹¹⁷ Racism or implicit bias may therefore influence physicians’ decisions about which patients should receive potentially life-saving treatments.

III. Because social inequities and racism exacerbate COVID-19 morbidity and mortality in minoritized populations, considering a patient’s BIPOC race or ethnicity in evaluating their risk of severe progression is justified.

Contrary to the plaintiff’s assertions, *see* Pl. Memorandum at 7, as discussed above, a wealth of evidence supports the Prioritization Guidance’s recommendation that healthcare providers in exercising their own clinical judgment consider a COVID-19 patient’s BIPOC race or ethnicity in evaluating risk of progressing to severe symptoms.¹¹⁸ Although race is a social construct and not an inherent biologic or genetic trait, as discussed above, BIPOC people experience higher rates of severe COVID-19 symptoms, hospitalizations, and death from COVID-19 than white people as a result of myriad factors, including social drivers of health. Moreover, research shows that, among people who have medical conditions such as heart disease and diabetes—two of the most common underlying medical conditions among COVID-19 patients—

¹¹⁴ *Just Medicine*, *supra* note 24, at 66–67, 165, 167.

¹¹⁵ William J. Hall et al., *supra* note 108, at e60.

¹¹⁶ Jennifer L. Wiltz, *supra* note 63, at 99.

¹¹⁸ *See* Prioritization Guidance, *supra* note 1, at 3.

BIPOC individuals' conditions tend to be less well-treated, deadlier, and more severe than white individuals'.¹¹⁹ BIPOC COVID-19 patients thus are at an increased risk of developing severe symptoms that the Prioritization Guidance's remaining risk factors, such as age and presence of underlying medical conditions alone, do not account for.

To illustrate, suppose a Black individual with heart disease and high blood pressure is eligible for one or more of the COVID-19 treatments during a time of low supply. The Prioritization Guidance suggests a healthcare provider consider the patient's heart disease as a risk factor.¹²⁰ But this consideration alone does not capture the likelihood that the Black individual's heart condition manifested earlier, and is more severe than, a white individual's of the same age with the same condition. Nor does this consideration alone account for the Black individual's increased risk of developing heart failure,¹²¹ increased risk of inflammation, or any of the other increased risks associated with their race that do not apply to a similarly situated white COVID-19 patient. Given these risks and the increased rates of severe illness and death from COVID-19 associated with BIPOC race or ethnicity, it is appropriate for healthcare professionals to take that information into account, along with other relevant factors in their clinical judgment, when evaluating a COVID-19 patient's risk of progressing to severe illness, including for resource allocation purposes.¹²² "Expanding the definition of 'most at risk' [for COVID-19] to include

¹¹⁹ See *supra* notes 22–26, 85, 87, 99.

¹²⁰ See Prioritization Guidance, *supra* note 1, at 2 (hyperlinking risk factors to CDC web page listing risk factors); CDC, *People with Certain Medical Conditions*, *supra* note 21 (listing "heart conditions such as heart failure" as a medical condition that increases a person's risk of getting severely ill from COVID-19).

¹²¹ Daniel Pan et al., *The impact of ethnicity on clinical outcomes in COVID-19: A systematic review*, EClinicalMedicine, June 3, 2020, at 6, bit.ly/34PffqU.

¹²² See Matthew A. Raifman & Julia R. Raifman, *Disparities in the Population at Risk of Severe Illness From COVID-19 by Race/Ethnicity and Income*, 59 Am. J. Preventive Med. 137, 137 (2020), doi.org/10.1016/j.amepre.2020.04.003.

social factors is critical to implementing equitable interventions and saving lives.”¹²³

The mechanism by which the Prioritization Guidance recommends healthcare professionals consider, using their clinical judgment and discretion, a COVID-19 patient’s BIPOC race or ethnicity—by including it as one of the risk factors for severe illness¹²⁴—is justified by both the strong correlation between BIPOC race or ethnicity and increased rates of severe illness from COVID-19 as well as the potential influence of racism or implicit bias within the medical system. In New York, Black persons experience at least twice the rate of death from COVID-19 and at least four times the rate of hospitalization from COVID-19 than white persons. This increased prevalence is similar to the increase in risk of patients with obesity and patients with a history of smoking,¹²⁵ two other risk factors under the Prioritization Guidance. Medical practitioners may consider a patient’s race or ethnicity, along with other social determinants of health, in making treatment decisions where justified by the evidence. For example, the American College of Obstetricians and Gynecologists and the Society for Maternal-Fetal Medicine’s recommendations regarding low-dose aspirin prophylaxis for the prevention of preeclampsia

¹²³ Rima A. Afifi et al., *supra* note 30, at 1.

¹²⁴ Prioritization Guidance, *supra* note 1, at 3. By its terms, the Prioritization Guidance notes that “Non-white race or Hispanic/Latino ethnicity should be considered a risk factor.” This brief provides the court with the current evidence regarding the disproportionately high prevalence and severity of COVID-19 cases among BIPOC and Latinx people. It should not be read as suggesting that race in and of itself is a genetic or biologic factor that causes medical risk; rather, as the Prioritization Guidance itself acknowledges, it is “longstanding systemic health and social inequities [that] have contributed” to increased prevalence of severe illness and death. *Id.* at 3. There are also other ways that may be effective to consider or describe the social consequences of race and ethnicity.

¹²⁵ See Lyudmyla Kompaniyets et al., *Body Mass Index and Risk for COVID-19–Related Hospitalization, Intensive Care Unit Admission, Invasive Mechanical Ventilation, and Death — United States, March–December 2020*, 70 MMWR 355 (2021), bit.ly/34cIXWG; Roengrudee Patanavanich & Stanton A. Glantz, *Smoking is associated with worse outcomes of COVID-19 particularly among younger adults: a systematic review and meta-analysis*, BMC Pub. Health, Aug. 16, 2021, doi.org/10.1186/s12889-021-11579-x.

consider “Black race (as a proxy for underlying racism)” a risk factor.¹²⁶ However, it is important to reiterate that race is a social construct, rather than an inherent biological trait, and when race is described as a risk factor, it is more likely to be a proxy for influences including structural racism than a proxy for genetics.

Because racism and implicit racial and ethnic biases are known to inform medical care, thereby contributing to healthcare disparities and inequities, medical professional associations such as the American Medical Association have called for “acknowledging the harm caused by racism and unconscious bias within medical research and health care” and “identifying tactics to counter racism and mitigate its health effects.”¹²⁷ By suggesting that healthcare professionals take a COVID-19 patient’s race or ethnicity into account, the Prioritization Guidance can help counteract racism and negative implicit biases against people of color that might otherwise inappropriately influence healthcare professionals’ prioritization decisions. Incorporating equity into “scarce resource allocation protocols,” as the Prioritization Guidance does, also accords with researchers’ and CDC’s recommendations,¹²⁸ and medical professional organizations’ principles of patient-centered care.¹²⁹ COVID-19’s disproportionate impact on BIPOC individuals is, moreover, an issue of public health. Allocating treatment to those known to have the most adverse

outcomes will alleviate the crisis of hospital overcrowding and demands on our healthcare system.¹³⁰

Indeed, if medical professionals fail to consider BIPOC individuals' increased risk of getting severely ill or dying from COVID-19, along with other relevant factors, in prioritizing COVID-19 treatments during times of low supply, that would likely result in BIPOC COVID-19 patients continuing to get severely ill and to die from COVID-19 at disproportionately higher rates relative to white patients; in effect, their risk would be underappreciated. Only by accounting for the increased risk of severe illness from COVID-19 that BIPOC individuals face will their assigned risk group accurately reflect their level of risk.¹³¹

CONCLUSION

For the reasons stated above and in Defendant's filings, *Amici* urge this Court to deny Plaintiff's motion for a preliminary injunction and grant Defendant's motion to dismiss.

Respectfully submitted,

s/ Rachel L. Fried
